Data availability is indicated by the transitions themselves on one or more of the data wires depending on the type of multi-rail encoding instead of with a request signal as in the bundled-data encoding. Examples include speculative completion which has been applied to design parallel prefix adders faster than synchronous ones, and a high-performance double-precision floating point adder which outperforms leading synchronous designs. **Circuits, Signals, and Systems by William M. Siebert**

This type of circuit is contrasted with , in which changes to the signal values in the circuit are triggered by repetitive pulses called a. The processor is intended for use in , whose chips are currently limited in size to those small enough that they can remain perfectly rigid.

**Circuits, Signals and Systems for Bioengineers**

The lectures are designed to pursue a variety of goals in parallel: to familiarize students with the properties of a fundamental set of analytical tools; to show how these tools can be applied to help understand many important concepts and devices in modern communication and control engineering practice; to explore some of the mathematical issues behind the powers and limitations of these tools; and to begin the development of

the vocabulary and grammar, common images and metaphors, of a general language of signal and system theory. There is no central clock with billions of dumb nodes dissipating useless power.
