speciation

We believe that isolation of marine populations within these deep tropical basins during glacial low-water events promoted extensive genetic diversification, and this why the Indo-Pacific region contains the largest number of species of marine organisms on the planet.

Speciation in the sea : a symposium/ edited for the Association by J.P. Harding & Norman Tebbel

To investigate the potential for lateral body photophores to contribute to species recognition, we examined the photophore patterns of myctophid lanternfishes that are conserved across taxa in both number and position, and are hypothesized to be homologous structures based on positional and structural homology criteria Ray ; Rémane ; Paxton. Furthermore, the data available from the fossil record can be better integrated with neontological data.

Speciation in the sea : a symposium/ edited for the Association by J.P. Harding & Norman Tebbel

This work adds to our understanding of how life thrives and evolution shaped present-day biodiversity in the deep sea, the largest and arguably least explored habitat on earth.
