Small mineral inclusions are often found in the material, which, when they are at the surface of the stone, become oxidised to a rust colour in some places. Of particular interest is the use of stratigraphic and structural geology, mineralogy, petrology, isotopic analysis and petrofabric analysis in order to derive cultural inference from the examination of quarries and mines. Note the lack of well-developed cement between grains and the resultant abundance of sutured grain contacts.

Correlation of right-laterally displaced gravity and magnetic anomalies that now have components at San Francisco and on the shelf north of Point Arena indicates that the presently active strand of the San Andreas fault north of the San Francisco peninsula formed recently at about 5 Ma when the triple junction jumped eastward a minimum of 100 km to its present location at the north end of the San Andreas fault.

Documentation of the material culture associated with the Aswan quarries is as of yet mainly available for the West Bank Bloxam et al. In order to determine the age of the relatively younger fans, the erosion rate of the boulders and the cosmogenic nuclide inheritance from exposure prior to deposition in the fan were established.

. Although the quarry landscape has been designated for supervision by SCA after intervention by the authors in 2002, it will be severely

threatened once the landreclamation resumes.
