

Life in the oceans

F. Watts - Without the Moon, Would There Be Life on Earth?

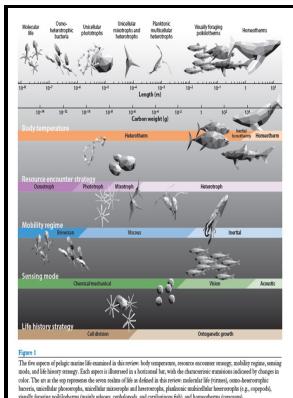

Figure 1
The figure shows species of prokaryotic marine life organized in five columns based on body temperature, sensory mechanism, sensing mode, and life history strategy. Each species is illustrated in a horizontal bar, with the characteristic dimension indicated by a scale in meters. The size of the bar represents the size of life as defined in the review molecular life forms, some developmental stages, and some life histories. The figure illustrates the diversity of life in the ocean, from tiny bacteria to large organisms, ranging from prokaryotes (mainly viruses, eukaryotes, and archaea) to fish, and from terrestrial through to aquatic environments.

Description: Examines plant and animal life, minerals, and other riches below the surface of the ocean, and the potential havoc that humans can wreak in harvesting resources from the seas.

The exposed land occupies the remaining 29 percent of the planetary surface and has a mean elevation of about 840 metres approximately 2,755 feet. For a full description of the water in the oceans, see. Indeed, many researchers do not recognize them either.

But four billion years ago a cooling Earth already had an ocean, but remained barren. If, however, life originated in tidal waters, he says, then tidal cycles could have played a major role.

The liquid phase predominates on Earth. Their ebb and flow pay homage to the cyclic nature of the cosmos along even the most secluded seashores.
